Why MRDTs?

Observed-Removed (OR) set CRDT

- **OR set**
  - A concurrent set where add-wins in a concurrent add(e) and rem(e)

Concrete state := $(\Sigma_a, \Sigma_r) \xrightarrow{\text{add}(a)} (\Sigma_a \cup \{(a, id)\}, \Sigma_r)$ where id is fresh

$$(\Sigma_a, \Sigma_r) \xrightarrow{\text{rem}(a)} (\Sigma_a, \Sigma_r \cup \{\ (a, id) \mid (a, id) \in \Sigma_a\ \})$$

$$(\Sigma_a, \Sigma_r) \xrightarrow{\text{read}()} \{a \mid (a, id) \in \Sigma_a \backslash \Sigma_r\}$$

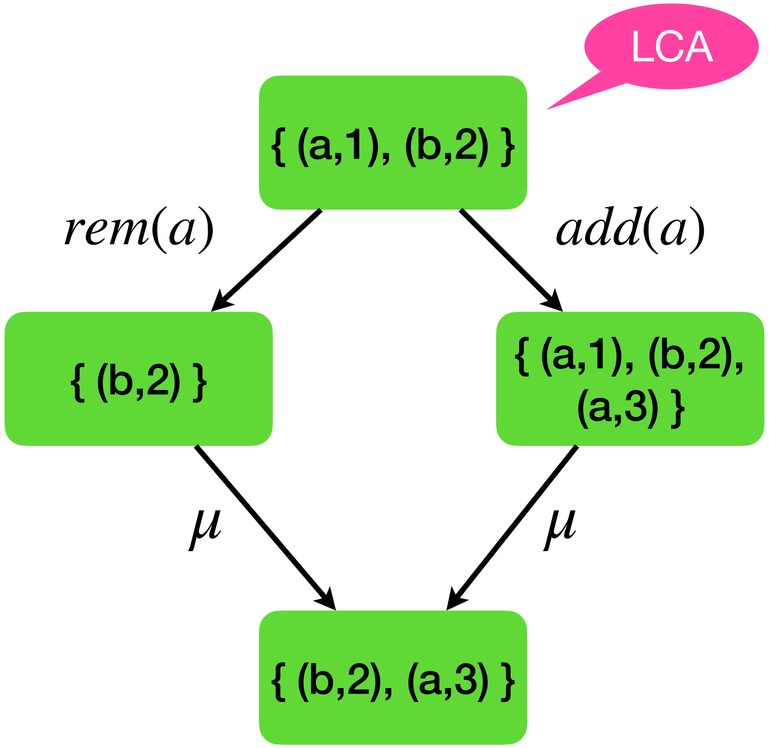
Tombstones

- States are asynchronously broadcast to other replicas

$$(\Sigma_a, \Sigma_r) \xrightarrow{\text{merge}(\Sigma'_a, \Sigma'_r)} (\Sigma_a \cup \Sigma'_a, \Sigma_r \cup \Sigma'_r)$$

- Space usage $O(|\text{adds}|)$

OR Set MRDT



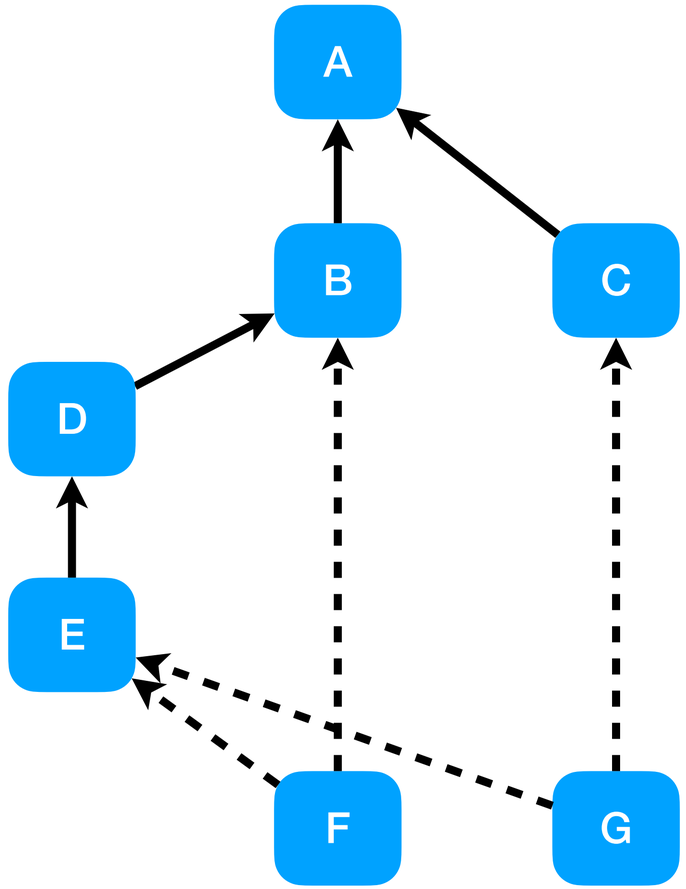
- Associate ***timestamp (id)*** with the element
- Add associates a ***fresh*** timestamp with the element
- Remove removes all matching elements with ***any id***
  - ***Removed from the concrete state!***
- Read returns the set removing ids

```
let merge lca v1 v2 =
  (lca ∩ v1 ∩ v2) (* unchanged or removed elements *)
  ∪ (v1 \ lca) (* added elements on left *)
  ∪ (v2 \ lca) (* added elements on right *)
```

- Space usage $O(|\text{adds} \cap \text{live}|)$
  - Duplicates — same element with different ids

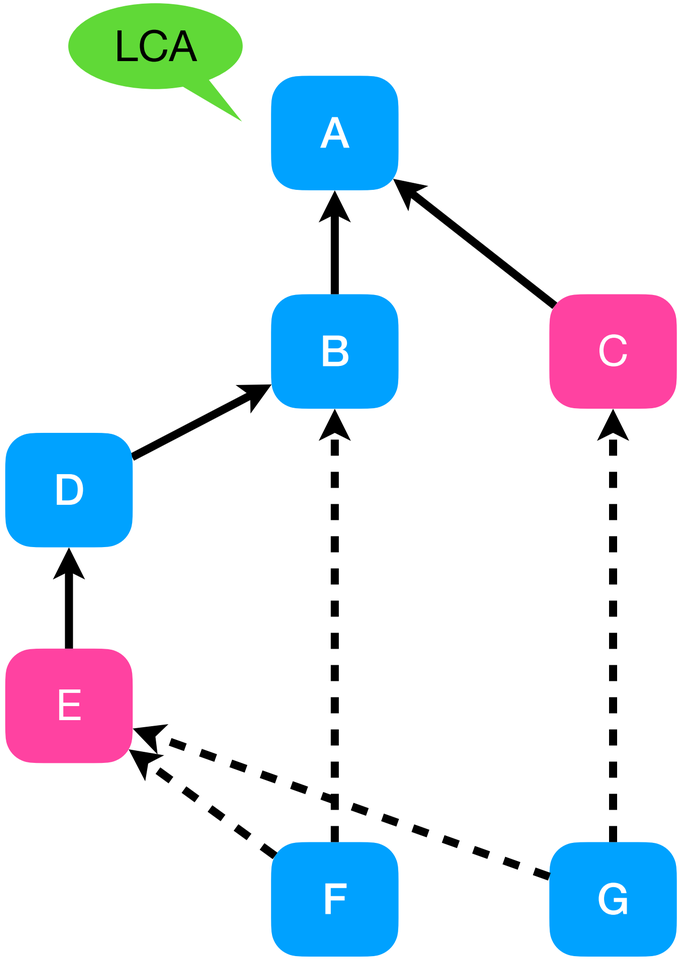
Runtime Support

- How did we eliminate tombstones?
  - Swept under the rug — MRDT runtime.
- MRDT runtime
  - Git-like distributed store with branching and merging
  - Support 3-way merge with lowest common ancestor (LCA)



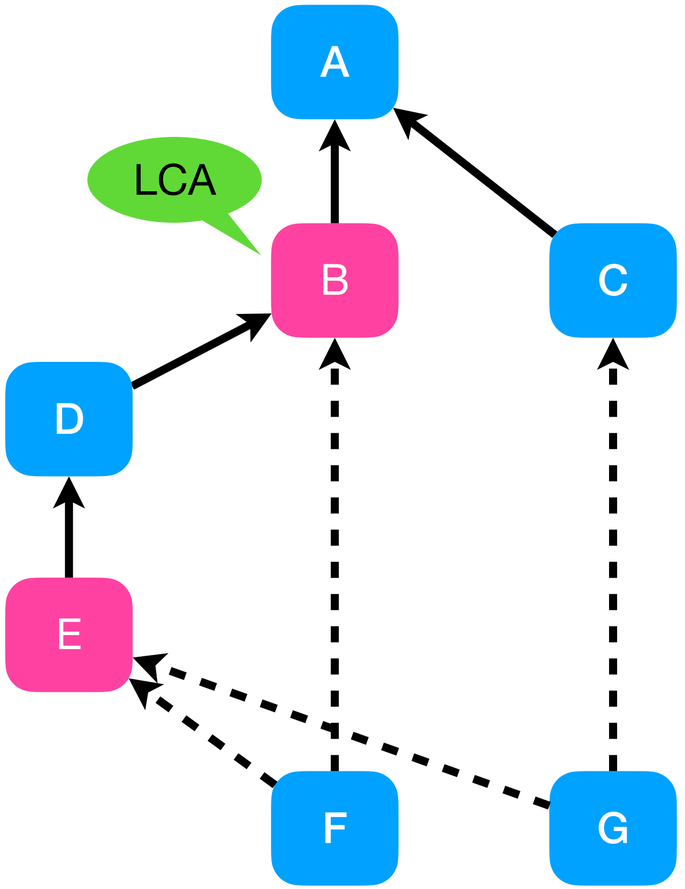
Runtime Support

- How did we eliminate tombstones?
  - Swept under the rug — MRDT runtime.
- MRDT runtime
  - Git-like distributed store with branching and merging
  - Support 3-way merge with lowest common ancestor (LCA)
    - LCA of E & C is A



Runtime Support

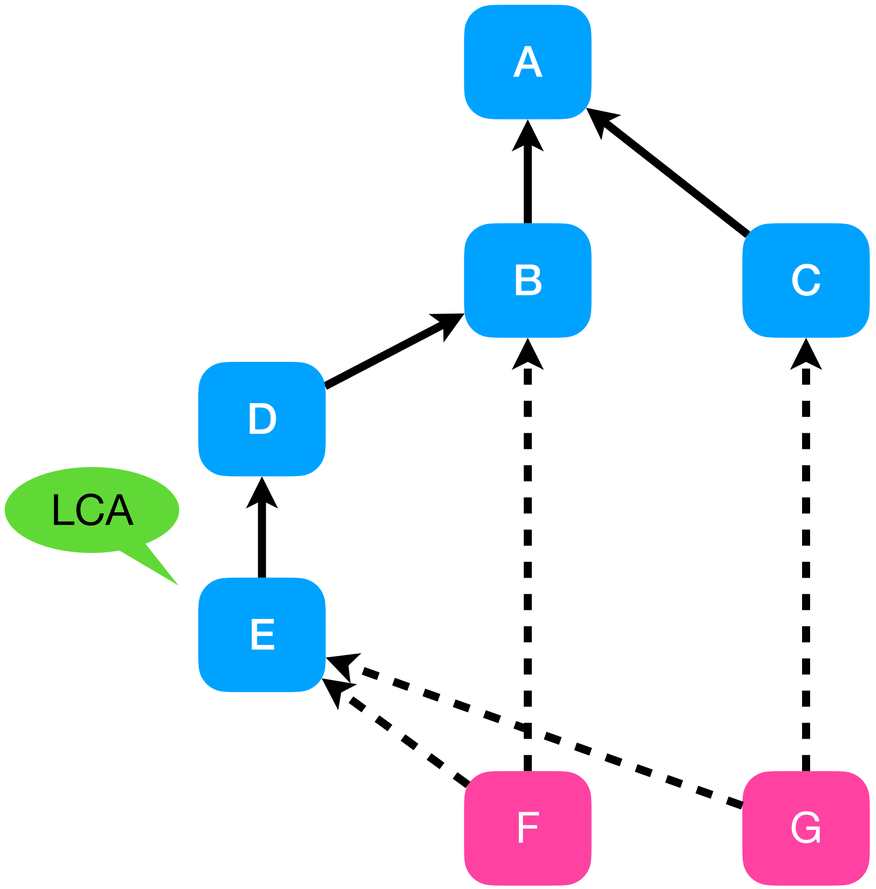
- How did we eliminate tombstones?
  - Swept under the rug — MRDT runtime.
- MRDT runtime
  - Git-like distributed store with branching and merging
  - Support 3-way merge with lowest common ancestor (LCA)
    - LCA of E & C is A
    - LCA of E & B is B



Irmin

Garbage collection of histories

- If **F** and **G** were the only two replica states
  - Only the LCA **E** is needed for any future merge



Garbage collection of histories

- If **F** and **G** were the only two replica states
  - Only the LCA **E** is needed for any future merge
- Asynchronously garbage collect all previous commits
  - And associated states

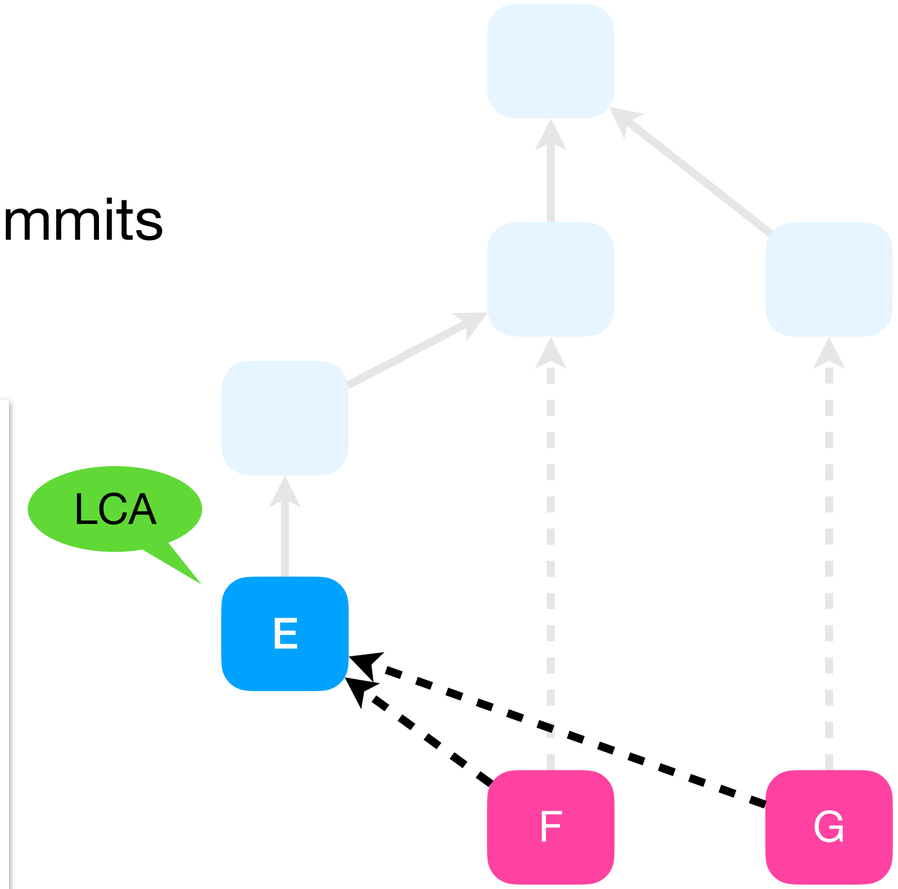
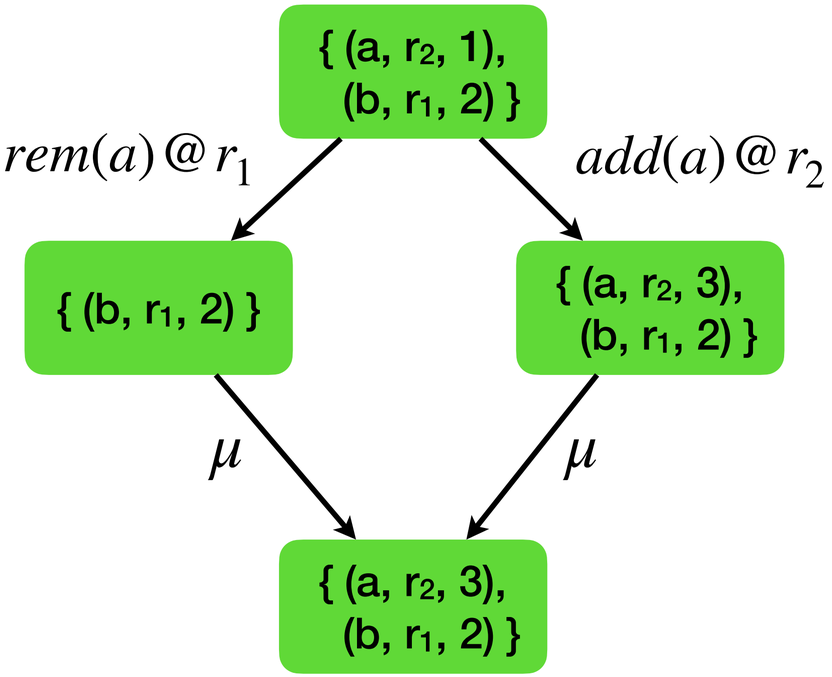
APLAS 2020

Abstract. Programming loosely connected distributed applications is a challenging endeavour. Loosely connected distributed applications such as geo-distributed stores and intermittently reachable IoT devices cannot afford to coordinate among all of the replicas in order to ensure data



Efficient OR set MRDT



- Elements tagged with ***replica id*** and ***timestamp***
- **add(e)** @ replica r,
  - Remove any **(e, r, ts)** for any **ts**
  - Add **(e, r, ts')** for a fresh timestamp **ts'**
- Remove, read and merge remain similar.
- Space usage $O(|\text{live}| \,.\, n)$
  - Duplicates — same element from different replicas

Not the first efficient OR set

Abstract

Conflict-Free Replicated Data-Types (CRDTs) [6] provide greater safety properties to eventually-consistent distributed systems without requiring synchronization. CRDTs ensure that concurrent, uncoordinated updates have deterministic outcomes via the properties of bounded join-semilattices.

- 1st PaPoC
  - When it was PaPEC!
- State-based CRDT in Riak
- ***And buggy!***

Buggy Riak DT Map

Unsound Optimizations

Implementing CRDTs can be quite challenging. Not only does the developer who is implementing CRDTs must ensure that updates to lattices are *inflationary* – ensuring the data structure is always moving up the lattice with respect to each change – but also that the merge function must be both *deterministic* and compute the *least-upper-bound*. We have even got this wrong a few times ourselves.

Abstract

Designing correct replicated data types (RDTs) is challenging because replicas evolve independently and must be merged while preserving application intent. A promising approach is correct-by-construction development in a proof-oriented programming language such as F*, Dafny and Lean, where

and Mergeable Replicated Data Types (MRDTs) [9] are widely used to implement such replicated state. However, designing correct RDTs is subtle. Even well-known designs such as Replicated Growable Arrays (RGA) [10] have had serious anomalies discovered after publication[1].

Replication-aware (RA) linearizability [21] provides a principled correctness condition for CRDTs, relating replica exe-

Convergence alone is insufficient

Merge function μ

$$\mu(a, b) = \mu(b, a) \quad \text{Commutativity}$$
$$\mu(a, a) = a \quad \text{Idempotence}$$
$$\mu(\mu(a, b), c) = \mu(a, \mu(b, c)) \quad \text{Associativity}$$

Satisfies algebraic properties

```
let merge v1 v2 = max v1 v2
```

Intent is not captured

Certified mergeable replicated data types

Authors: Vimala Soundarapandian, Adharsh Kamath, Kartik Nagar, KC Sivaramakrishnan | Authors Info & Claims

PLDI 2022: Proceedings of the 43rd ACM SIGPLAN International Conference on Programming Language Design and Implementation
Pages 332 - 347 • https://doi.org/10.1145/3519939.3523735

- **Abstract state** = events + visibility (partial order)
- **Operations** = folds over abstract state

Specification

Simulation relation

MRDT operations +
3-way merge function

Implementation

A proof-oriented SMT-aided programming language

Abstract state of a data type

An abstract state for a data type $\tau = (Op_\tau, Val_\tau)$ is a tuple

$$I = \langle E, oper, rval, time, vis \rangle,$$

where

$E \subseteq Event$ (set of events),

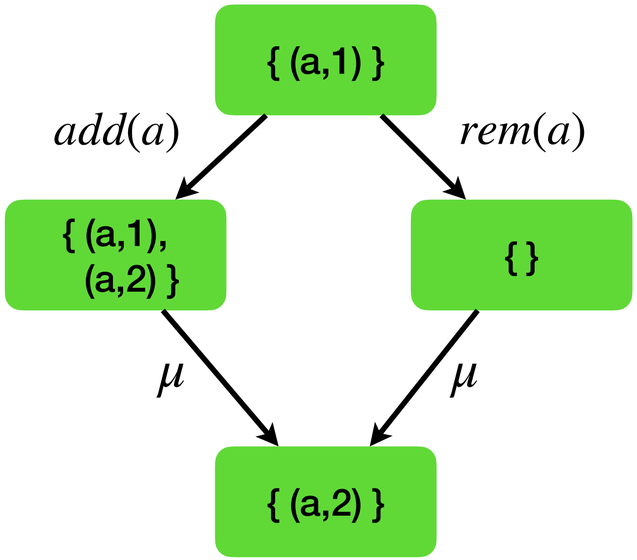
$oper : E \to Op_\tau$ (operation of each event),

$rval : E \to Val_\tau$ (return value of each event),

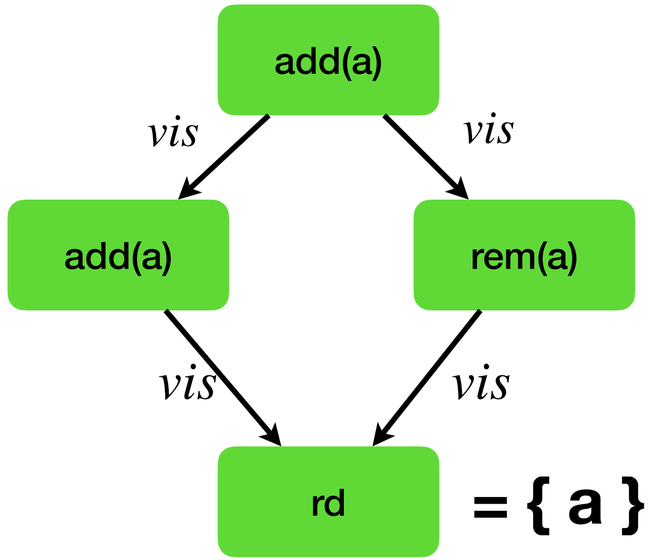
$time : E \to Timestamp$ (timestamp of each event),

$vis \subseteq E \times E$ (visibility relation).

Specifying OR set behaviour



Concrete state



Abstract state

$$\mathcal{F}_{orset}(\mathsf{rd}, \langle E, oper, rval, time, vis \rangle) = \{\, a \mid \exists e \in E\,.\, oper(e) = \mathsf{add}(a) \wedge \neg(\exists f \in E\,.\, oper(f) = \mathsf{remove}(a) \wedge e \xrightarrow{vis} f) \,\}$$

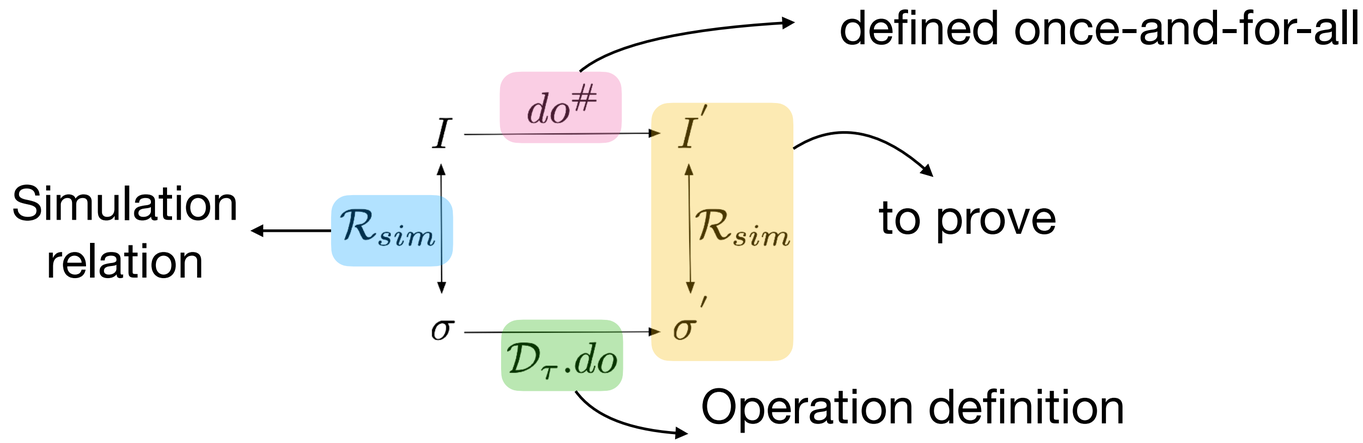
Simulation Relation for OR set

- Connect the abstract and the concrete state

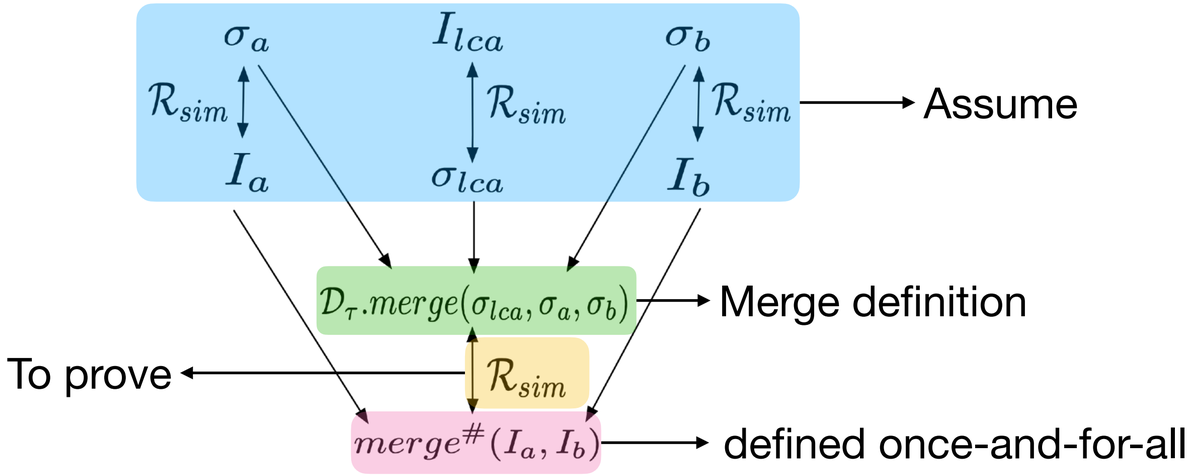
$$\mathcal{R}_{sim}(I, \sigma) \iff (\forall (a, t) \in \sigma \iff (\exists e \in I.E \wedge I.\, oper(e) = add(a) \wedge I.time(e) = t \wedge \neg(\exists f \in I.E \wedge I.\, oper(f) = remove(a) \wedge e \xrightarrow{vis} f)))$$

Verification

- Prove that the simulation holds for operations



- Prove that the simulation holds for merge



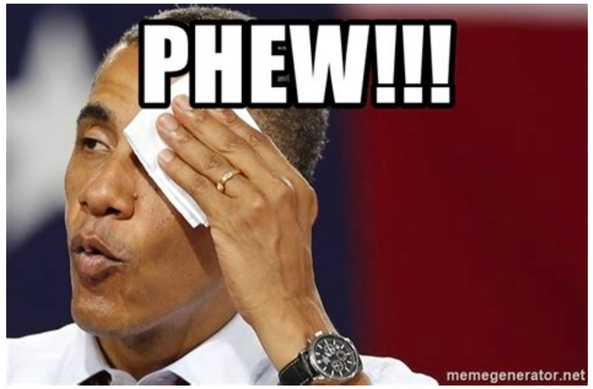
Verification (not done yet)

- Prove that the specification and the implementation agree on the return values of operations

$$\forall I, \sigma, e, op, a, t.\, \mathcal{R}_{sim}(I, \sigma) \wedge \mathcal{D}_{\tau}.do(op, \sigma, t) = (\sigma', a) \\ \wedge \Psi_{ts}(I) \implies a = \mathcal{F}_{\tau}(op, I)$$

- Prove convergence

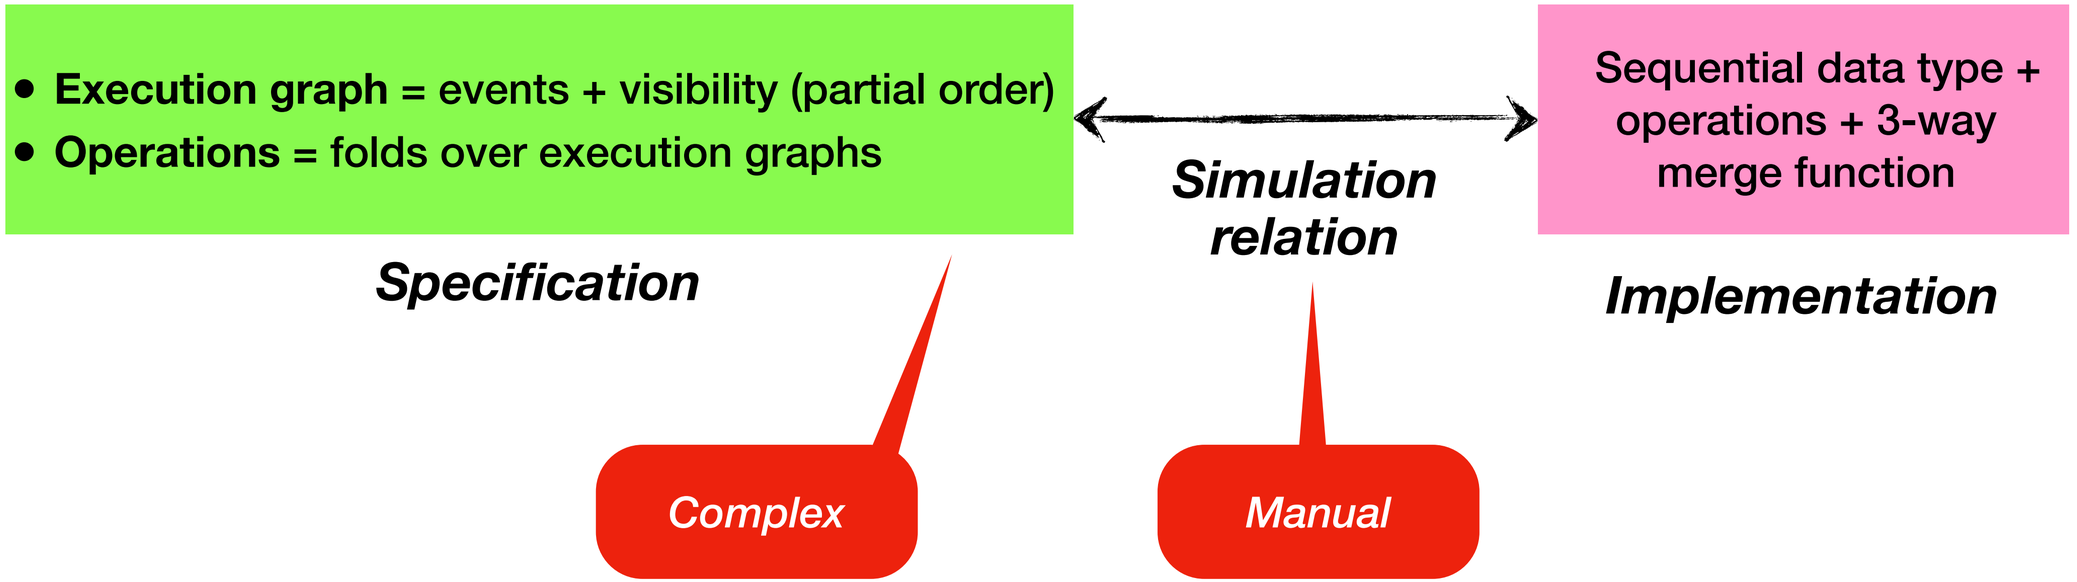
$$\forall I, \sigma_a, \sigma_b.\, \mathcal{R}_{sim}(I, \sigma_a) \wedge \mathcal{R}_{sim}(I, \sigma_b) \implies \sigma_a \sim \sigma_b$$



Verified MRDTs using Peepul

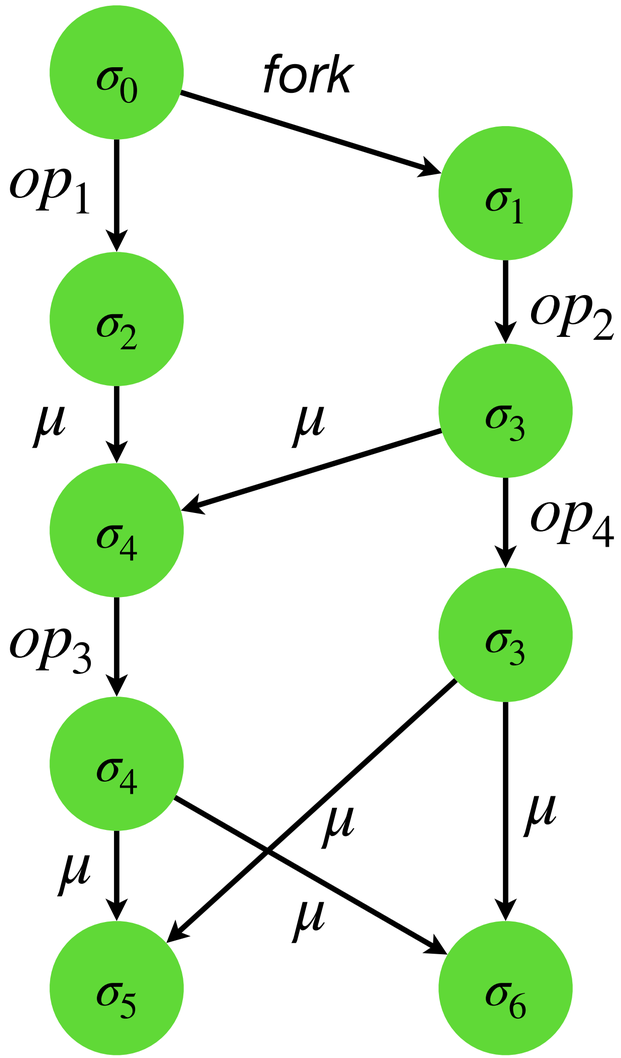
MRDTs verified	#Lines code	#Lines proof	#Lemmas	Verif. time (s)
Increment-only counter	6	43	2	3.494
PN counter	8	43	2	23.211
Enable-wins flag	20	58	3	1074
		81	6	171
		89	7	104
LWW register	5	44	1	4.21
G-set	10	23	0	4.71
		28	1	2.462
		33	2	1.993
G-map	48	26	0	26.089
Mergeable log	39	95	2	36.562
OR-set (§2.1.1)	30	36	0	43.85
		41	1	21.656
		46	2	8.829
OR-set-space (§2.1.2)	59	108	7	1716
OR-set-spacetime	97	266	7	1854
Queue	32	1123	75	4753

Challenges with Peepul



- Queue specification more complicated than the implementation
  - Recovering a queue structure from a partially-ordered soup of events is HARD!
- Proofs are manual
  - F* isn't great for manual proofs

Is there a more natural spec?



$\sigma_5 = \sigma_6 = \text{linearization}(\{op_1, op_2, op_3, op_4\})\ \sigma_0$

Replication-aware Linearizability

RESEARCH-ARTICLE

Replication-aware linearizability

Authors: Chao Wang, Constantin Enea, Suha Orhun Mutluergil, Gustavo Petri | Authors Info & Clai

PLDI 2019: Proceedings of the 40th ACM SIGPLAN Conference on Programming Language Design and Implementation
https://doi.org/10.1145/3314221.3314617

- Replica states should be a ***linearisation*** of observed ***update*** operations
  - Linearisation total order lo compatible with partially-ordered visibility relation vis
  - No real-time ordering requirement unlike traditional linearizability
- Payoff
  - If a replicated object is RA-linearizable, reason about it using ***sequential semantics***

Using RA-linearizability for verification

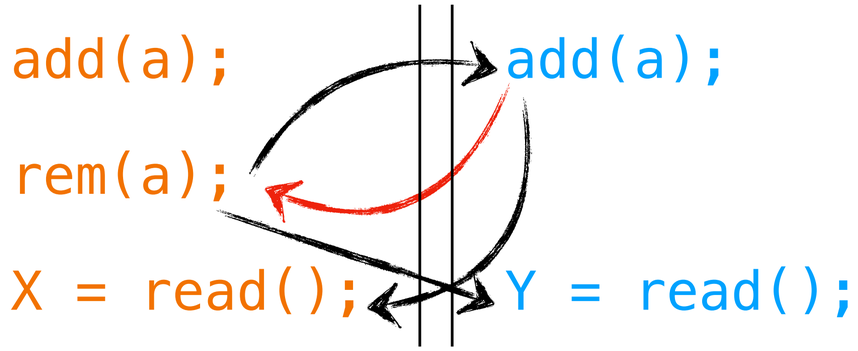
```
add(a);      ||  add(a);
rem(a);      ||
X = read();  ||  Y = read();
```

$$a \in X \implies a \in Y$$

- Since Add-wins set is RA-linearizable, you can use ***totally ordered trace*** and the ***sequential reasoning***

```
add(a);      rem(a);      add(a);      X = read();    Y = read()
  {a}          {}           {a}          X = {a}        Y = {a}
```

Using RA-linearizability for verification



$$a \in X \implies a \in Y$$

- Let's try to make the statement false
  - Make $a \in X$ true and $a \in Y$ false

Replication-aware Linearizability

RESEARCH-ARTICLE

Replication-aware linearizability

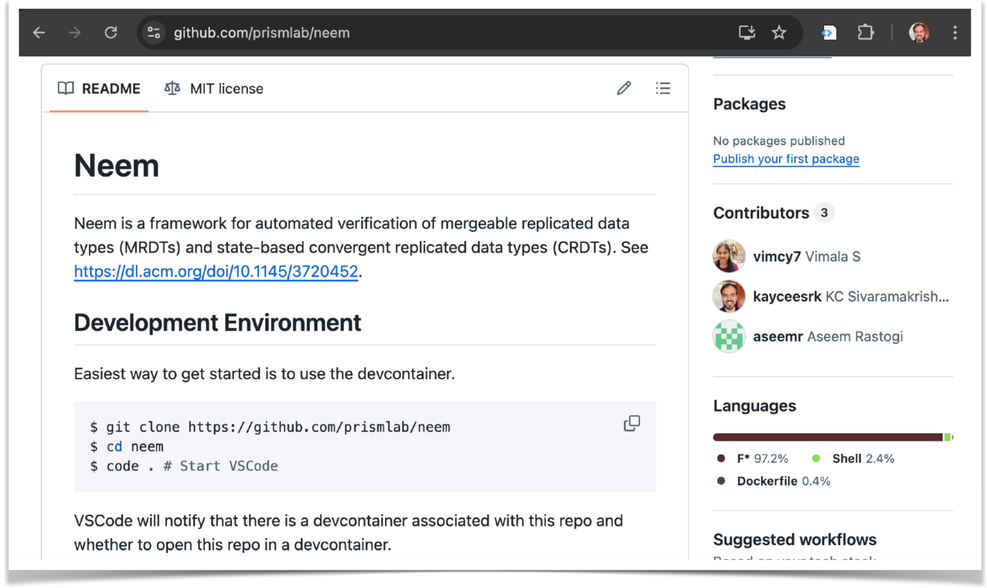
Authors: Chao Wang, Constantin Enea, Suha Orhun Mutluergil, Gustavo Petri | Authors Info & Clai

PLDI 2019: Proceedings of the 40th ACM SIGPLAN Conference on Programming Language Design and Implementation
https://doi.org/10.1145/3314221.3314617

- Presented a proof methodology to show that a CRDT is linearisable
- Not automated or mechanised

Neem: Automatic verification of RDTs

- Definition of RA-linearizability for MRDTs
- A novel induction scheme for MRDTs and state-based CRDTs to ***automatically*** verify RA-linearizability
- Implemented in F*



Specifying RDTs in Neem

- Not all operations commute
  - **Add-wins set** — `add(a)` and `rem(a)` do not commute
  - Specify ordering using the **Conflict Resolution** relation $rc = \{(rem_a, add_a) \mid a \in \mathbb{E}\}$
  - Linearization order lo must be compatible with rc for concurrent events
- Neem developers provide
  - MRDT = Sequential Data Type + 3-way merge
  - Conflict Resolution rc relation

Add-wins Set

State $\Sigma = \mathcal{P}(\mathbb{E} \times \mathcal{T})$

Updates $O = \{\text{add}_a, \text{rem}_a \mid a \in \mathbb{E}\}$

Queries $Q = \{\text{rd}\}$

Init State $\sigma_0 = \{\}$

Update behaviour

$$\text{do}(\sigma, t, \_, \text{add}_a) = \sigma \cup \{(a, t)\}$$

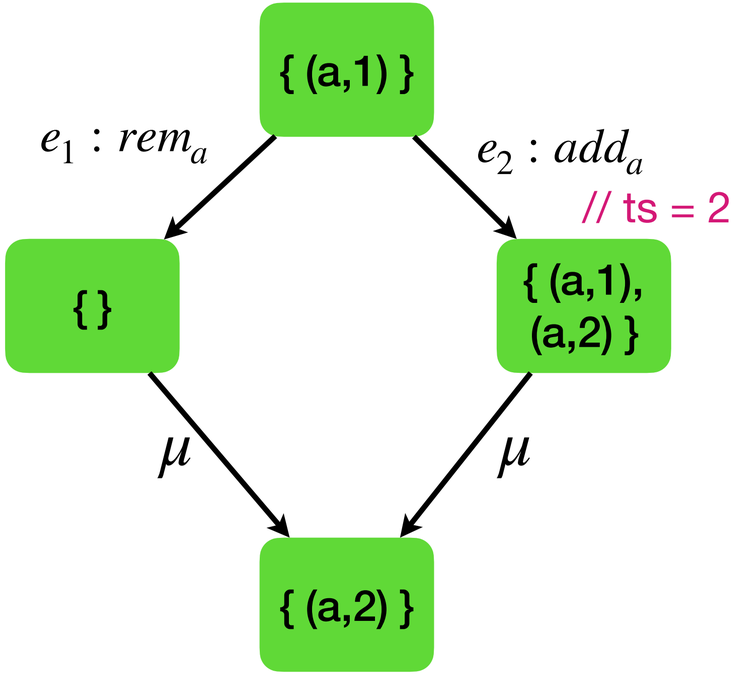
$$\text{do}(\sigma, \_, \_, \text{rem}_a) = \sigma \backslash \{(a, i) \mid (a, i) \in \sigma\}$$

Merge

$$\text{merge}(\sigma_\top, \sigma_1, \sigma_2) = (\sigma_\top \cap \sigma_1 \cap \sigma_2) \cup (\sigma_1 \backslash \sigma_\top) \cup (\sigma_2 \backslash \sigma_\top)$$

Query behaviour $\text{query}(\sigma, rd) = \{a \mid (a, \_) \in \sigma\}$

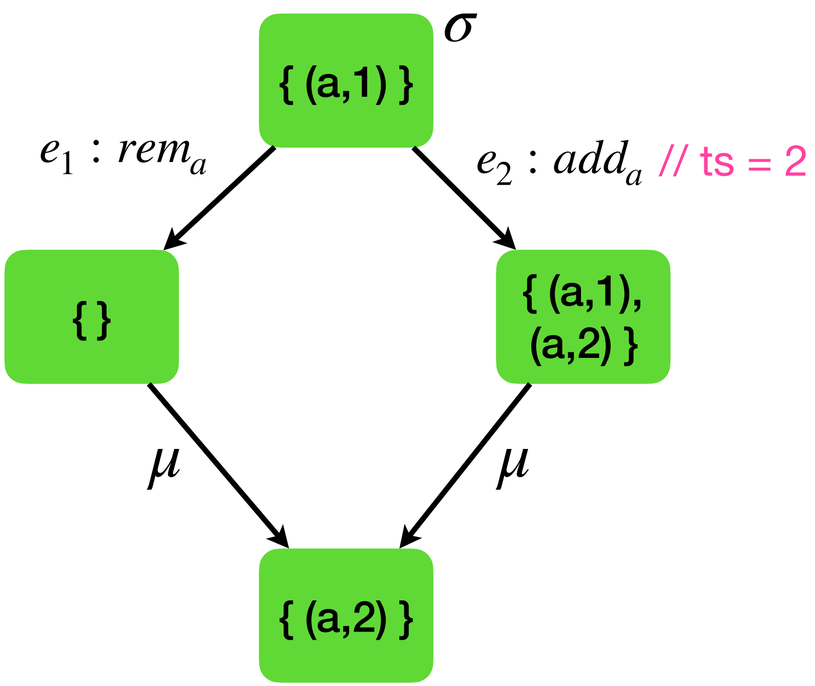
Resolve conflict $\text{rc} = \{(\text{rem}_a, \text{add}_a) \mid a \in \mathbb{E}\}$



$$\{(a,2)\} = add_a(rem_a\{(a,1)\})$$

Bottom up linearisation

$$rc = \{(rem_a, add_a) \mid a \in \mathbb{E}\}$$



To show

$$\mu(\sigma, e_1(\sigma), e_2(\sigma)) = e_2(e_1(\sigma))$$

Neem also supports verification of RA-linearizability of state-based CRDTs

https://github.com/prismlab/neem

Challenges with Neem

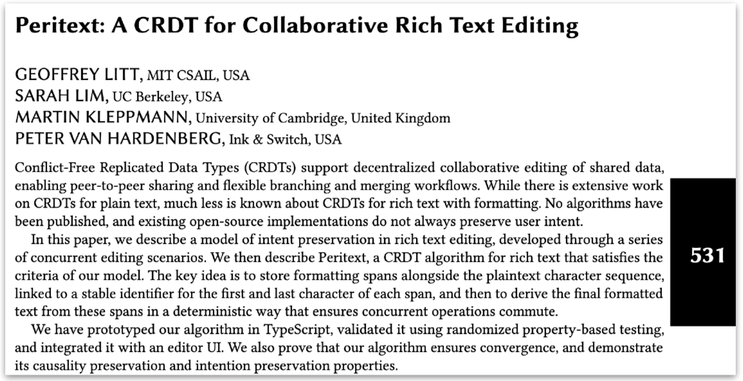
- Automated verification in F* returns yes / no / ¯_(ツ)_/¯
  - Not pleasant for engineering
  - No counterexamples!
- TCB includes the SMT solver
- F* SMT-aided proofs are brittle
  - Some lemmas need specific heuristics for fuel, unfolding, etc.
  - z3 upgrade breaks proofs!

Sal: Multi-modal verification of RDTs

- Move Neem from F* to Lean
- Advantages
  - Smaller TCB
  - Property-based testing
    - Counter-example generation and visualisation
- ***Agentic proof-oriented programming***
  - Fundamentally changing how we construct software
  - Coding Agents are great at Lean

Agentic Proof Oriented Programming in Sal

- Claude Opus 4.7, with Aristotle for hard proofs
- In the last couple of weeks, compared to the Sal paper
  - **13 new CRDTs and 2 new MRDTs** have been verified
- Including Peritext, Priority Queue, Bounded Counters



Peritext: A CRDT for Collaborative Rich Text Editing

GEOFFREY LITT, MIT CSAIL, USA
SARAH LIM, UC Berkeley, USA
MARTIN KLEPPMANN, University of Cambridge, United Kingdom
PETER VAN HARDENBERG, Ink & Switch, USA

Conflict-Free Replicated Data Types (CRDTs) support decentralized collaborative editing of shared data, enabling peer-to-peer sharing and flexible branching and merging workflows. While there is extensive work on CRDTs for plain text, much less is known about CRDTs for rich text with formatting. No algorithms have been published, and existing open-source implementations do not always preserve user intent.

In this paper, we describe a model of intent preservation in rich text editing, developed through a series of concurrent editing scenarios. We then describe Peritext, a CRDT algorithm for rich text that satisfies the criteria of our model. The key idea is to store formatting spans alongside the plaintext character sequence, linked to a stable identifier for the first and last character of each span, and then to derive the final formatted text from these spans in a deterministic way that ensures concurrent operations commute.

We have prototyped our algorithm in TypeScript, validated it using randomized property-based testing, and integrated it with an editor UI. We also prove that our algorithm ensures convergence, and demonstrate its causality preservation and intention preservation properties.

ABSTRACT

Internet-scale distributed systems often rely on replication to achieve fault-tolerance and load distribution. To provide low latency and high availability, the systems are often required to accept updates on one replica immediately and then propagate the updates among replicas asynchronously. Conflict-free Replicated Data Type (CRDT) is a principled approach to addressing the challenge for these systems to resolve conflicts among concurrent updates. Although many CRDTs have been studied, little research has been done on Conflict-free Replicated Priority Queue (CRPQ), which is a collection of elements that focuses on maintaining element orderings based on their priority values, and can be used in many applications scenarios such as task scheduling and network routing. In this work, we discuss the design rationales of CRPQs and introduce two CRPQ designs: Add-Win CRPQ and Remove-Win CRPQ. The correctness service availability are widely regarded as the most critical factors. To address the requirements of such applications, many distributed systems are designed for low latency and high availability in the first place [20, 24]. The server of the system handles the update requests immediately without communicating with remote replicas. The updates are propagated to remote replicas asynchronously.

These distributed systems achieve low latency and high availability by accepting weak consistency due to the CAP theorem [14, 19]. The *strong eventual consistency* is a widely accepted weak consistency that provides certain guarantees to developers of upper-layer applications [33]. It ensures that two replicas will reach the same state if they have received the same set of updates. The conflicts of concurrent updates are resolved during such process. Conflict-free Replicated Data Type (CRDT) is a framework for designing replicated data types that provide strong eventual consistency [29, 32]. It

INRIA / LIP6

***Abstract*—Geo-replicated databases often operate under the principle of eventual consistency to offer high-availability with low latency on a simple key/value store abstraction. Recently, some have adopted commutative data types to provide seamless reconciliation for special purpose data types, such as counters. Despite this, the inability to enforce numeric invariants across all replicas still remains a key shortcoming of relying on the limited guarantees of eventual consistency storage.**

correct operation [17]. Real world examples where enforcing invariants is essential are advertisement services, virtual wallets or to maintain stocks. However, enforcing this condition using counters implemented on eventually consistent cloud database is impossible. This is because counter updates can occur concurrently, making it impossible to detect if the limit is exceeded before the operation concludes.

Verified in TLA+

Weakness of Sal/Neem RA-linearizability

- Original RA-linearizability assumes that a separate sequential spec

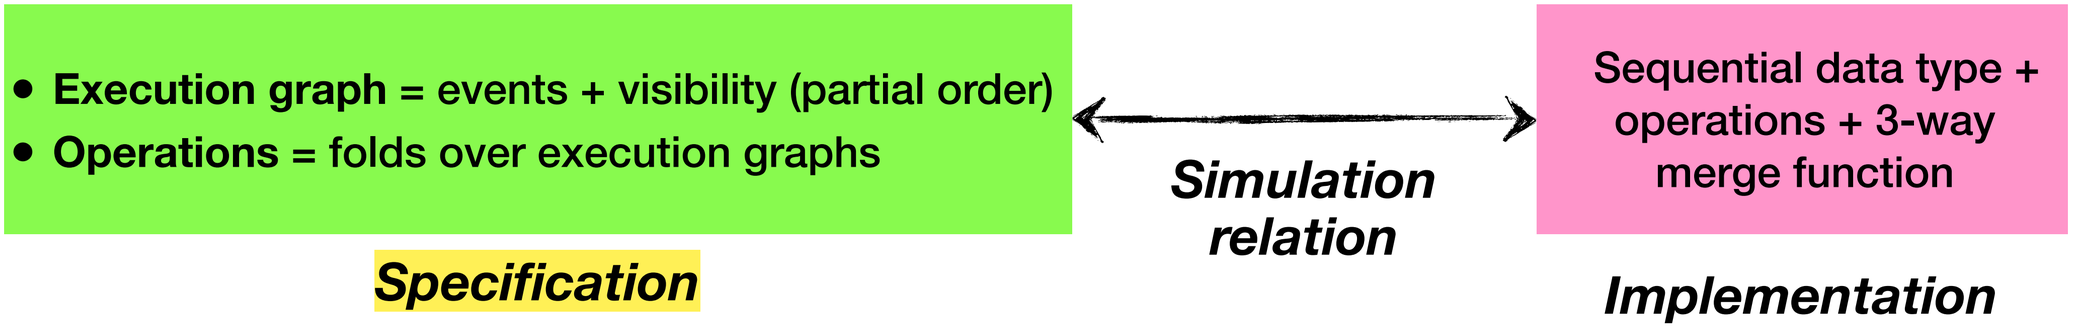
  A history $h = (E, vis)$, $E \subseteq \text{Queries} \uplus \text{Updates}$, is RA-linearizable w.r.t. a sequential specification Spec if there exists a total order seq on E (same events) such that:

  (i) $vis \cup seq$ is acyclic;

  (ii) $seq\downarrow_{Updates} \in$ Spec;

  (iii) $\forall \ell_{qr} \in E, \left(seq\downarrow_{\text{vis}^{-1}(\ell_{qr}) \cap Updates}\right) \cdot \ell_{qr} \in$ Spec.

- Peepul also expects a separate spec



Weakness of Sal/Neem RA-linearizability

- Sal/Neem RA-linearizability — ***operation definition itself as the sequential spec***
  - $\sigma_5 = \sigma_6 = \text{linearization}(\{op_1, op_2, op_3, op_4\})\ \sigma_0$
- Works well for RDTs where
  - Concrete state ~= sequential state & **do** operations are “correct”
  - For example, efficient OR set, counters, etc.
- However
  - Broken **do** operations, broken RDT
  - RDTs that use inflationary sets + read-side heavy lifting are trivially correct
    - RGA, Peritext, priority queue…

ReadSide Proofs for Intent Preservation

- Additional lean proofs on top of RA-linearizability
- In a multi-valued register
  - Sequential writes overwrite; concurrent writes are preserved
  - Neem implementation didn’t respect the former; ***Wasn’t caught!***
  - Caught by read-side proofs

```
/-- **Sequential write overwrites prior writes.** If a write at `ts₁`
is currently visible, and we apply `Write v₂ O₂` where `O₂` includes
`ts₁` (which is what a well-formed sequential write would do — its
prepare-time snapshot includes all currently-visible ts), then
`v₁` is no longer visible at the witness `ts₁`. -/
theorem sequential_write_supersedes
    (s : concrete_st) (v₁ v₂ ts₁ ts₂ rid : ℕ) (O₂ : set ℕ)
    (h_t1_in_O2 : mem ts₁ O₂ = true) :
    mem ts₁ (Prod.snd (do_ s (ts₂, rid, app_op_t.Write v₂ O₂))) = true := by
  simp only [mem] at h_t1_in_O2
  simp [do_, h_t1_in_O2]
```

```
/-- **Concurrent writes both survive (headline).** Two replicas
diverge from common state `s`. Each applies its own `Write` with a
snapshot that does NOT include the other's fresh `ts` (true by
`distinct_ops` for any reachable execution: each replica's snapshot
was taken before the other's write existed). After merge, both
`v₁` and `v₂` are visible.

Premise list:
  * The two new ts values are fresh (not in `s.writes`, not in `s.removed`).
  * Neither snapshot includes its own ts nor the other's ts.

These all hold structurally for any well-formed replica execution. -/
theorem concurrent_writes_both_visible
    (s : concrete_st) (v₁ v₂ ts₁ ts₂ rid₁ rid₂ : ℕ) (O₁ O₂ : set ℕ)
    (h_fresh_t1_O1 : mem ts₁ O₁ = false)
    (h_fresh_t2_O1 : mem ts₂ O₁ = false)
    (h_fresh_t1_O2 : mem ts₁ O₂ = false)
```

ReadSide Proofs — Peritext

Peritext: A CRDT for Collaborative Rich Text Editing

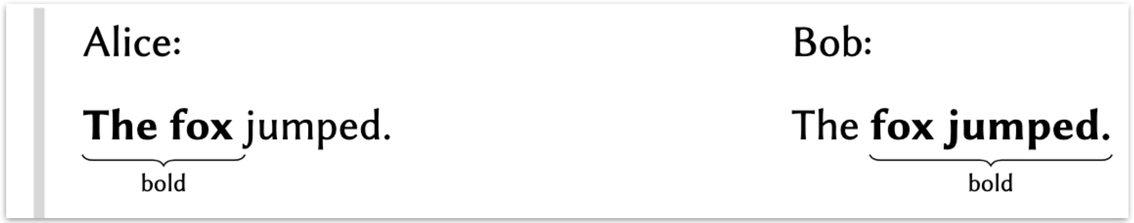
GEOFFREY LITT, MIT CSAIL, USA
SARAH LIM, UC Berkeley, USA
MARTIN KLEPPMANN, University of Cambridge, United Kingdom
PETER VAN HARDENBERG, Ink & Switch, USA

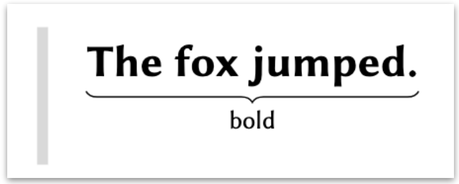
Conflict-Free Replicated Data Types (CRDTs) support decentralized collaborative editing of shared data, enabling peer-to-peer sharing and flexible branching and merging workflows. While there is extensive work on CRDTs for plain text, much less is known about CRDTs for rich text with formatting. No algorithms have been published, and existing open-source implementations do not always preserve user intent.

In this paper, we describe a model of intent preservation in rich text editing, developed through a series of concurrent editing scenarios. We then describe Peritext, a CRDT algorithm for rich text that satisfies the criteria of our model. The key idea is to store formatting spans alongside the plaintext character sequence, linked to a stable identifier for the first and last character of each span, and then to derive the final formatted text from these spans in a deterministic way that ensures concurrent operations commute.

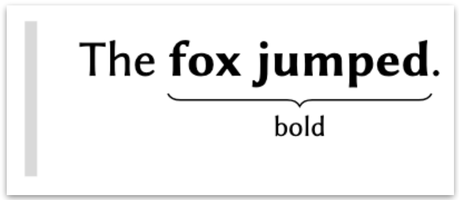
We have prototyped our algorithm in TypeScript, validated it using randomized property-based testing, and integrated it with an editor UI. We also prove that our algorithm ensures convergence, and demonstrate its causality preservation and intention preservation properties.

PeriText — Intent preservation





Concurrent overlapping marks



Text insertion at span boundaries

ReadSide Proofs — Peritext

Paper claim	Sal artifact	Status / notes
§A.1 Convergence	24 RA-linearizability VCs in `Peritext_CRDT.lean` and `Peritext_MRDT.lean` (`merge_comm`, `merge_idem`, `base_2op`, `ind_lca_2op`, `inter_*`, `ind_*`, `lem_0op`)	✅ All closed via `by sal`, kernel-checked. Universally quantified over op interleavings.
§3.1 Causality preservation	Framework assumption (causal delivery); `afters` map structurally encodes insert causality; `causal_order_visible_lt` (RGA readside) lifts it to visible-order	✅ Same convention as paper §3.1.
§A.2 Intent preservation — convergence at the read	`readRichText_visible_convergent`	✅ Read-side analogue of merge convergence.
§A.2 Ex 1 — insertion within a span	`insert_within_span_in_span_visible` + propagation lemmas	✅
§A.2 Ex 2 — overlapping same-type Adds	`partial_overlap_all_adds_formatted_visible`	✅
§A.2 Ex 3 — different mark types coexist	`different_type_adds_coexist_visible`	✅
§A.2 Ex 4 — same-type, different values (colors)	not formalised	⚠️ Requires `markValue` field on `MarkOp` — state-shape change.
§A.2 Ex 5 — bold vs non-bold conflict	`add_wins_over_concurrent_remove_visible` + `no_add_cover_implies_unformatted_visible`	✅ LWW by opId (paper §4.4).
§A.2 Ex 6 — overlapping comments via distinct markType	follows from `different_type_adds_coexist_visible`	✅
§A.2 Ex 7 — bold-boundary insertion expands	`ex7_bold_older_sibling_in_span` + `bold_expand_in_span_visible` (via `bold_expand_reach`)	✅
§A.2 Ex 8 — link-boundary insertion does not expand	`ex8_link_descendant_visible_lt_endId` + `_not_in_span_visible_of_wf`	✅ Uses `wf_afters` acyclicity.
(Beyond paper) Anchors survive tombstones	`anchors_survive_tombstones_visible`	✅ Implicit in §4.4 paper discussion.
